

## How Letters Are Used in Mathematics

Understanding the customary usage of letters in mathematics can greatly assist in interpreting the import of an equation or expression. For example—if there is a simple mixing of  $a, b, c,$  and  $x$  it is most likely that  $x$  represents a variable of unknown or unspecified value where as the  $a, b,$  and  $c$  are likely to be place holders for values that do not change. This article discusses the customary uses of letters in lower division mathematics.

**Constants.**  $\pi$  is used for the ratio of the circumference of a circle to its diameter. This value is constant for all circles (3.14159...).  $e$  is used for Euler's number (2.7182818...).  $i$  is used for the imaginary number  $\sqrt{-1}$ . Note that this is different from the custom in engineering where  $j$  is used for  $\sqrt{-1}$ .  $\aleph_0$  (aleph-naught) is the first transfinite number, i.e. denumerably infinite.  $\mathfrak{C}$  is used for the cardinality of the continuum, i.e.  $2^{\aleph_0}$ .

**Unspecified Constants.** The letters at the beginning of the alphabet, in particular  $a, b,$  and  $c,$  are used as placeholders for Real valued constants. If the emphasis is on the form of the equation then  $A, B,$  and  $C$  are often used. For integer valued constants we generally use  $n$  then  $m.$   $N$  is often used to indicate an arbitrarily large integer. In a number theory setting  $p$  and  $q$  are used for primes;  $q$  and  $r$  are used for quotient and remainder.

**Real Variables.** Real valued quantities which are unknown and expected to vary are represented by letters at the end of the alphabet. Unknowns with no specific environment are assigned in the order  $x, y, z, w, u,$  and  $v.$  The understanding is as follows:  
Only  $x$  in an equation— $x$  represents the values which make the equation true.  
Only  $x$  in an expression—function definition with  $x$  as the independent variable and domain as all values for which the expression evaluates to a Real number.  
Only  $x$  and  $y$  in an equation—(1)  $y$  is a (perhaps implicitly specified) function of  $x,$  or (2)  $(x,y)$  are the ordered pairs that make the equation true.  
Only  $x$  and  $y$  in an expression—a function of two variables  
Only  $x, y,$  and  $z$  in an equation— $z$  is a function of the two independent variables  $x$  and  $y.$   
 $x, y, z,$  and  $w$  in an equation— $w$  is a function of the three independent variables  $x, y,$  and  $z.$   
 $x,y$  and  $u,v$ —this is used for a mapping from  $\mathbb{R}^2 \rightarrow \mathbb{R}^2.$   $(x,y)$  is in the domain (independent variables) and  $(u,v)$  is the range (dependent variables).

**Real Variables with Understandings.** Unknown values from some special domains often have customary letters:  $t$  for time,  $s$  for arc length or linear position,  $r$  for radius (use  $\rho$  if  $r$  is already taken),  $A$  for area,  $V$  for volume,  $e$  for eccentricity,  $\theta$  for an angle (particularly the counterclockwise angle from the positive  $x$ -axis in the  $xy$  plane), other angle variables include  $\phi$  and  $\psi.$  For very small unknowns use  $\epsilon$  then  $\delta.$   $\lambda$  is used for unknown eigenvalues or for a wave length.  $\omega$  is used for frequency as in  $\sin(\omega t).$  For curvature use  $\kappa.$  For the angle measured down from the positive  $z$ -axis use  $\phi.$  For the standard deviation of a population use  $\sigma.$  For the mean of a population use  $\mu.$  For the

standard deviation of a sample use  $s$ .  $\Delta$  is used as a prefix to indicate “a small change in”. For the sides and opposite angles of a triangle it is common to use  $A, B, C$  with  $a, b, c$  (or  $\alpha, \beta, \gamma$ ). Direction cosine angles in three space with respect to  $x, y, z$  are given by  $\alpha, \beta,$  and  $\gamma$  respectively.

**Integer Variables.** Integer variables are generally assigned in the order  $i, j,$  and  $k$ .

**Complex Variables.**  $z$  is used instead of  $x$  as the primary unknown for complex variables.  $a$  and  $b$  are used as the real and imaginary parts of a complex number.  $\theta$  is used as the principle angle.  $i$  is used as the imaginary constant.

**Functions.** Real valued functions are assigned in the order  $f, g,$  then  $h$ . When the emphasis is less on the mapping aspect of the function then common usage is--  $y$  as a function of  $x$ ;  $u$  as an intermediate function of  $x$ ;  $z$  as a function of  $x$  and  $y$ ; and  $w$  as a function of  $x, y,$  and  $z$ . For “parametric equations”  $x, y,$  and  $z$  become the dependent variables of the independent variables  $s, t, s$  and  $t,$  or  $u$  and  $v$ . In this case  $s$  is preferred for arc length and  $t$  is preferred for time.  $P(\text{event description})$  is the probability of that event.  $N(\cdot)$  is the Normal (Gaussian) distribution with parameters mean and standard deviation.  $B(\cdot)$  is the Binomial distribution with parameters  $p$  (success probability) and  $n$  (number of trials). Polynomial functions often are given with  $p(x)$  and  $q(x)$  or  $P(x)$  and  $Q(x)$ .  $\delta$  is used for the dirac delta operator ( $\delta(i,j) = 1$  if  $i=j,$  zero otherwise).

**Operators.** The term “operator” is used for functions whose domain is other functions.  $d/dx$  is derivative with respect to  $x,$   $d/dt$  is derivative with respect to  $t,$  etc.  $d$  is the differential operator. Suffix  $'$  is used when the “with respect to” variable is understood as in  $y'$  means the derivative of  $y$  with respect to  $x$ .  $\Sigma$  is the summation operator.  $\Pi$  is the product operator. For general matrices use  $A, B, C$  in that order. For linear transformations use  $T$  or  $L$ .

**Special Usages.**  $o$  (letter oh) and  $l$  (letter el) are avoided because of their potential confusion with  $0$  (number zero) and  $1$  (number one). If letter  $l$  is required then it is often given in a script font as  $\ell$ . Letter like symbols that resemble  $R, C, Q,$  or  $Z$  (e.g.  $\Re$ ) signify the Real numbers, Complex numbers, Rational numbers, or Integers respectively.  $\phi$  or  $\Phi$  is used for the empty set.
